[Basic QuantumATK Tutorial](#)
[ATK Reference Manual](#)

In this tutorial you will learn how to obtain the piezoelectric tensor and its coefficients with QuantumATK. Specifically, you will:

1. compute the piezoelectric tensor;
2. calculate the e_{33} coefficient by following these steps:
 - calculate the changes in the relevant structural parameters due to strain;
 - compute the piezoelectric tensor in the clamped-ion approximation and extract the coefficient $e_{33}(0)$;
 - compute the Born effective charge.

Introduction

Piezoelectric materials exhibit an induced electric polarization upon the application of external macroscopic strain. The polarization can be reversed by applying an external electric field. These materials find application in a variety of Microelectromechanical Systems (MEMS).

In this tutorial we are going to study the piezoelectric constant of AlN. This synthetic ceramic material is used in a variety of MEMS such as Surface Acoustic Wave sensors (SAWs), and Film Bulk Acoustic Resonators (FBAR).

The piezoelectric tensor

The piezoelectric tensor

In the absence of external fields, the total macroscopic polarization P of a solid is the sum of the spontaneous polarization P_{eq} (strain independent) of the equilibrium structure, and of the piezoelectric polarization induced by strain P_p (strain dependent).

$$P = P_{eq} + P_p$$

The piezoelectric tensor can be expressed as:

$$\gamma_{\delta\alpha} = \frac{\Delta P_{\delta}}{\Delta \epsilon_{\alpha}}$$

In QuantumATK

$\gamma_{\delta\alpha}$ is calculated using a finite-difference approach and

P is calculated using a Berry-phase approach. You can refer to the [Polarization](#) tutorial for more information on how

P is evaluated using modern theory of polarization.

Computing the piezoelectric tensor

The first thing you should do is to import the AlN (Hexagonal) structure in the **Stash**, optimize its bulk structure and change the cell geometry to Orthorhombic. In this tutorial, you will use a AlN (Orthorhombic) bulk optimized at PBE using FHI pseudopotentials and DZP basis set.

Create a new **QuantumATK project**, and download the HDF5 file containing the optimized structure: ([AlN_orthorhombic.hdf5](#)). Save it in the **Project Folder** and its content will become visible in the **LabFloor**.

1. Go to **Scripter** and double click the  *Analysis from File* and  *PiezoelectricTensor* (click Analysis ► PiezoelectricTensor) blocks to add them to the script.

2. Double-click the  *Analysis from file* block and select the object containing the optimized bulk structure (object id: *gID001*), as shown below.

The predicted value for e_{33} is 1.4849 C/m². This value is in good agreement with the value found in the literature (1.46 C/m²). [1]

In the next section we are going to see how you can calculate e_{33} in an alternative way.

Alternative way of calculating the piezoelectric coefficient e_{33}

The piezoelectric coefficient e_{33} can be also calculated as the sum of two terms [1] [2]:

1. the clamped-ion term $e_{33}(0)$, that expresses the electronic response to strain.
2. a second term describing the effect of the internal strain on the piezoelectric polarization.

The complete expression for e_{33} thus reads:

$$e_{33} = e_{33}(0) + \frac{4eZ^*}{\sqrt{3}a^2} \frac{du}{d\epsilon_3}$$

where

e is the electronic charge,

ϵ_3 is the macroscopic applied strain and

Z^* is the Born effective charge, which depends on the change in polarization upon the displacement of an ion (or rather, a periodic sublattice of equivalent ions):

$$Z_{\nu,i,j}^* = \frac{\Omega}{|e|} \frac{\partial P_t^i}{\partial r_j^\nu}$$

where

Ω is the unit cell volume,

P_t^i is the total polarization along the Cartesian direction

i , and

r_j^ν is the coordinate of ion

ν in direction

j . The Born effective charge is also referred to as effective charge or dynamical charge.

Note

The Born effective charge is a tensor. In fact, when an ion is displaced in direction \hat{j} , this will clearly affect the polarization in same direction \hat{j} . However, it may also lead to a change in polarization in another direction \hat{i} perpendicular to \hat{j} .

In the calculations below the derivative will be approximated using finite differences:

$$\frac{\partial P_t^z}{\partial r_z^\nu} \approx \frac{P_t^z(+\delta\hat{z}, \nu) - P_t^z(-\delta\hat{z}, \nu)}{2\delta},$$

where

$P_t^z(\pm\delta\hat{z}, \nu)$ is the polarization along the z-direction when atom ν has been displaced by the amount δ in the positive/negative z-direction.

In the following, we will obtain e_{33} by calculating each term explicitly. Specifically, we will:

1. calculate the variation of the interatomic distance due to strain $\left(\frac{du}{d\epsilon_\alpha}\right)$;
2. compute the piezoelectric constant in the clamped-ion approximation $e_{33}(0)$;
3. compute the Born effective charge Z^* .

The variation of the interatomic distance due to strain

The AlN hexagonal cell

This variation is expressed as

$\frac{du}{d\epsilon_\alpha}$ where

du represents the difference in the interatomic distance

u (

$du = u' - u$) and

$d\epsilon_3$ represents the applied strain (

$d\epsilon_3 = c' - c$) in the direction parallel to the bond.

In order to calculate

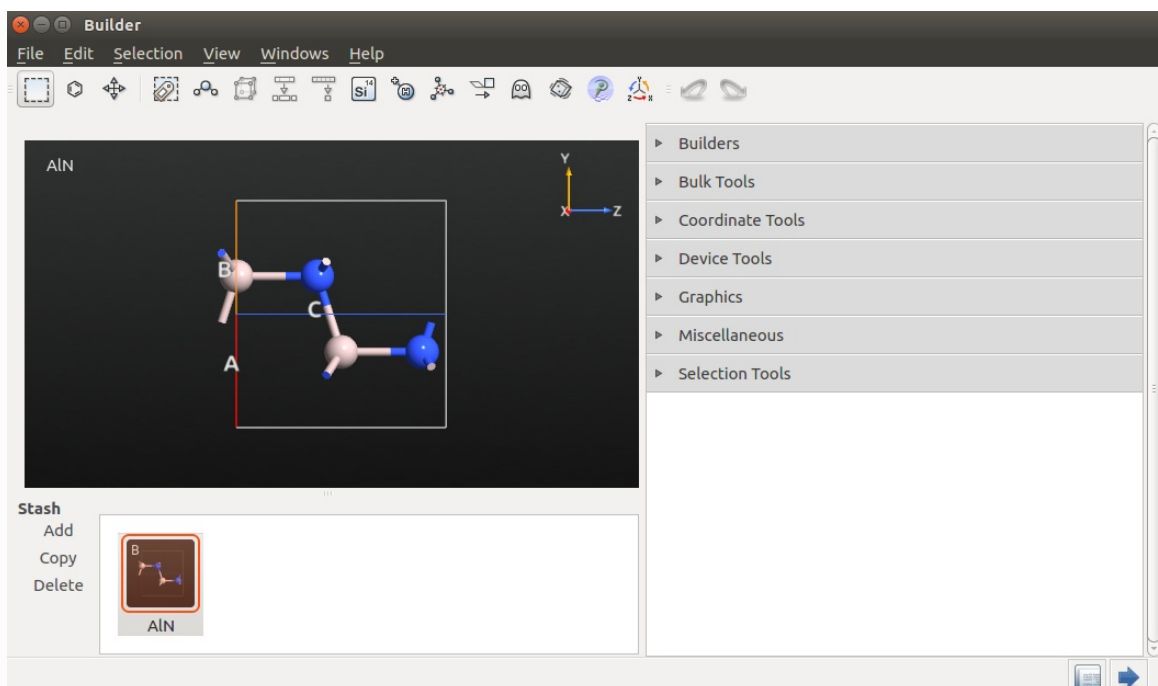

du we will:

1. relax the bulk structure and calculate u ;
2. apply a 1% strain to the unit cell in c direction, relax the internal parameters and get the interatomic distance under strain, u' .

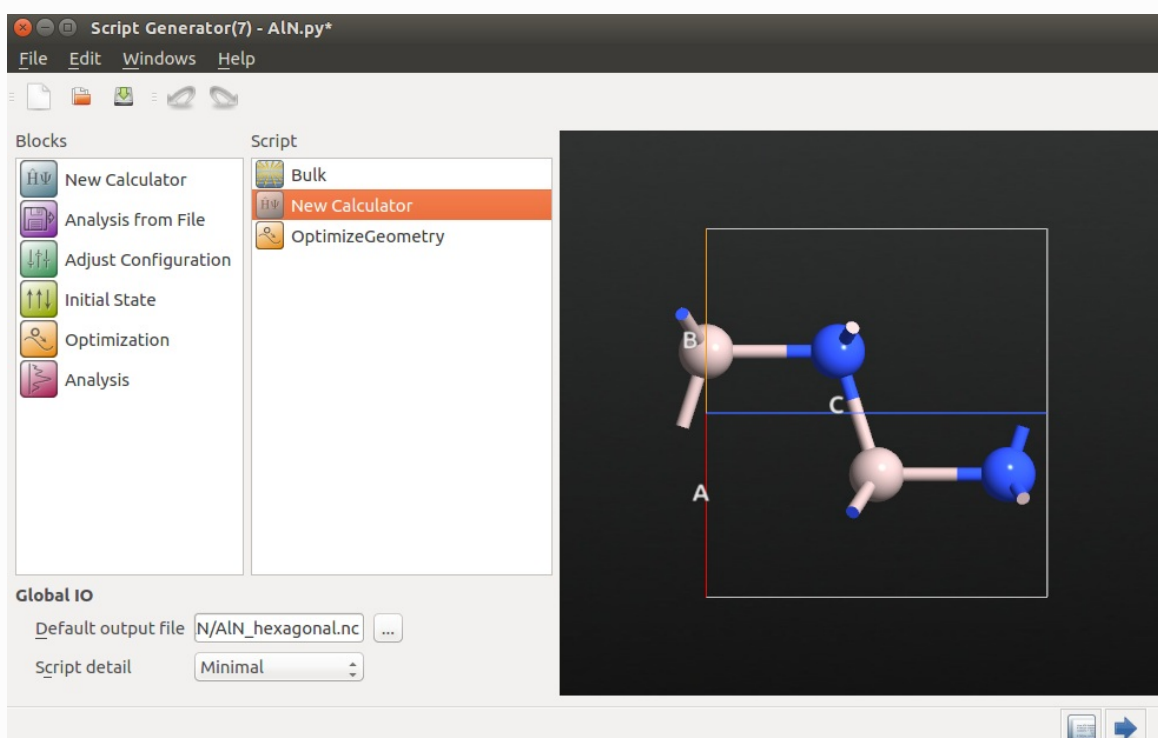

Calculating the interatomic distance

u for the relaxed system

1. Go to **Builder** and click Add ► Form Database, locate "AlN (Hexagonal)" in the database, and add it to the **Stash**.

2. Send the bulk configuration to the **Script Generator**.
3. In the Script Generator, double-click the *New Calculator* and *OptimizeGeometry* (click Optimization ► Optimize Geometry) blocks to add them to the script.

4. In the *New Calculator* block set the following parameters:

- *exchange and correlation*: GGA.PBE
- *Basis set*: DZP
- *k-point sampling*: (9,9,9)

The table below shows the relaxed structural parameters.

Table 5 Table: Relaxed cell parameters in¶

	QuantumATK	Bernardini <i>et al.</i> [1]
a	3.116	3.0766
c	5.007	4.9810
c/a	1.607	1.6190
u/c	0.381	0.380

The value of the relaxed c lattice constant is 5.007 Å. In the next step, we will apply a 1% compressive strain in the c direction by diminishing the lattice constant in c direction in 0.05 Å.

Internal relaxation under strain in z direction

1. Send the relaxed structure to the **Builder** and rename it as `AlN_hexagonal_strain.hdf5`.

2. Go to Bulk Tools ► Lattice Parameters to decrease the lattice parameter in 1% in c direction.

×

7. Send the script to the **Job Manager** and run the script.

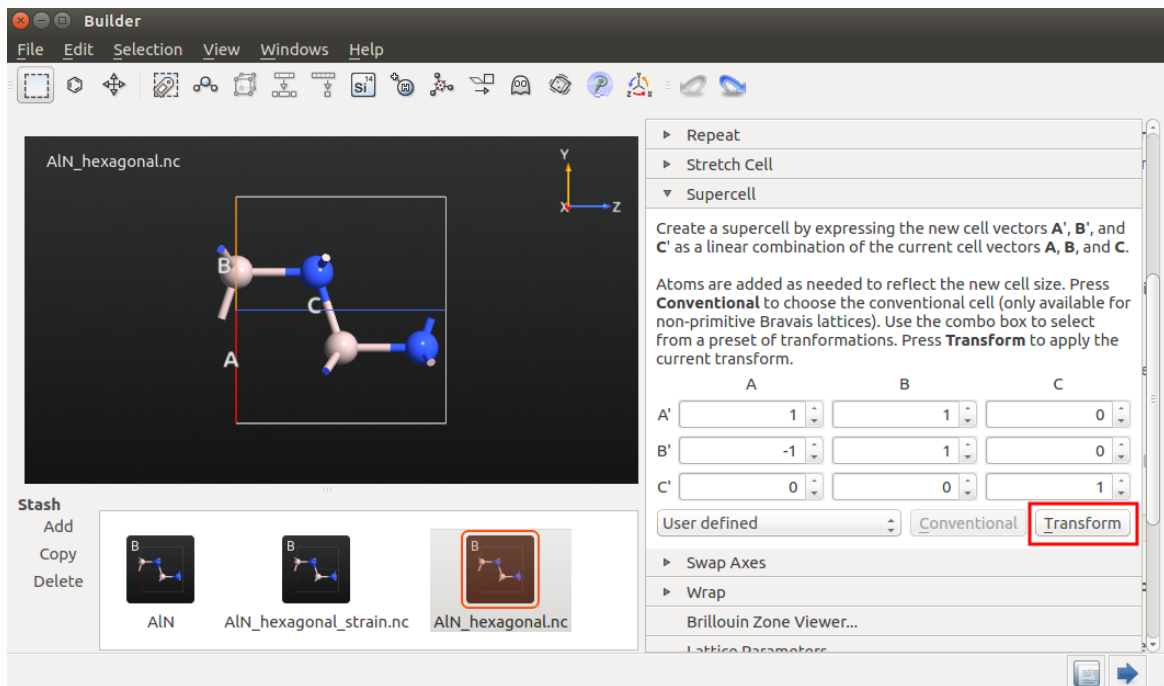

Once the calculation is finished, select the optimized bulk structure in the **LabFloor** and click the **Viewer** plugin to visualize the parameters.

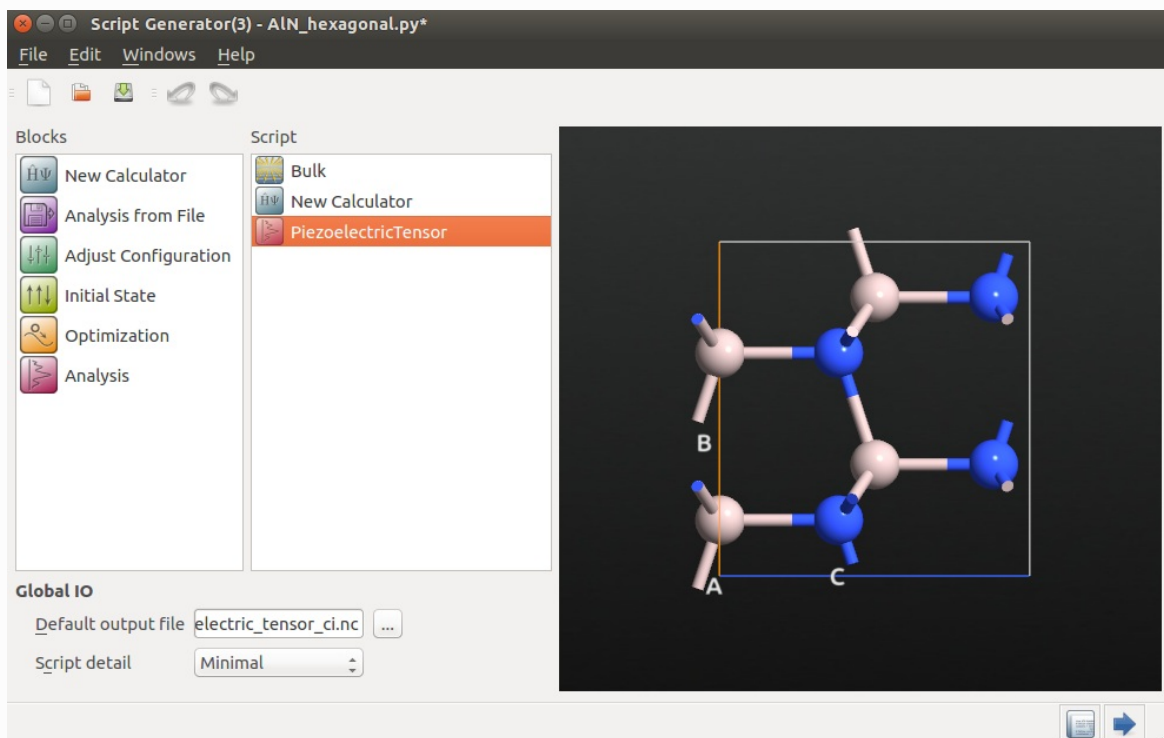

The predicted u' value is 1.89985 Å, and therefore the predicted $\frac{du}{d\epsilon_3}$ value is -0.1866. This value is in agreement with the value found in the literature (-0.18) [1].

Computing the piezoelectric tensor in the clamped-ion approximation

1. Send the relaxed structure to the **Builder**.
2. In the **Builder**, go to Bulk Tools ► Supercell to transform the cell according to the figure below.

3. Send the bulk configuration to the **Script Generator** and add the *New Calculator* and the *PiezoelectricTensor* blocks to the script.

4. In the *New Calculator* block set the following parameters:
 - *exchange and correlation*: GGA.PBE
 - *k-point sampling*: (9,9,9)
5. In the *PiezoelectricTensor* block set a [(19,9,9), (9,19,9), (9,9,19)] k-point sampling as shown below.

The predicted

$e_{33}(0)$ value is -0.4424 C/m^2 , which is in good agreement with the value found in the literature [1].

Computing the Born effective charge

In order to compute the Born effective charge in QuantumATK, you need to use the script provided here ([born_charges.py](#)).

```

1 #read saved configuration
2 configuration0 = nlread('piezoelectric_tensor_ci.hdf5', object_id='gID000')[0]
3
4 # Get the fractional coordinates of read configuration
5 R0 = configuration0.fractionalCoordinates()
6
7 # Get the elements
8 elements = configuration0.elements()
9
10 # Get the lattice
11 lattice = configuration0.bravaisLattice()
12
13 # From the lattice extract unit cell volume and length of lattice vector in z-direction
14 volume = lattice.unitCellVolume()
15
16 vectors = lattice.primitiveVectors()
17 c = vectors[2][2]
18
19 # Get the calculator
20 calculator = configuration0.calculator()
21
22 # Number of atoms
23 numberOfAtoms = len(R0)
24
25 # Fractional displacement in the +/- z direction
26 delta_z = 0.01
27
28 # Array for storing the calculated Born Charges
29 bornCharges = numpy.zeros(numberOfAtoms)
30
31
32 # Loop over atoms in unit cell
33 for nAtom in range(numberOfAtoms):
34     # Loop over displacement in positive/negative z-direction
35

```

```

36 # List with polarization values
37 Pz = []
38 for s in [1,-1]:
39     # Make a copy of the initial coordinates
40     R = R0.copy()
41
42     # Displace z-coordinate if atom 'nAtom'
43     R[nAtom,2] += s*delta_z
44
45     # Make a new configuration with the displaced atom
46     configuration = BulkConfiguration(bravais_lattice=lattice,
47                                     elements=elements,
48                                     fractional_coordinates=R)
49
50     # Set the calculator using the saved configuration as initial state
51     configuration.setCalculator(calculator,initial_state=configuration0)
52
53     # Update the configuration (DFT calculation)
54     configuration.update()
55
56     # Calculate polarization. Only use fine k-sampling in the z-direction
57     polarization = Polarization(configuration=configuration,
58                                kpoints_a=MonkhorstPackGrid(2,2,2),
59                                kpoints_b=MonkhorstPackGrid(2,2,2),
60                                kpoints_c=MonkhorstPackGrid(5,5,20),
61                                )
62
63     # Print polarization
64     nlprint(polarization)
65
66     # Get the total cartesian polarization

68
69     # Append the z-component to the Pz list
70     Pz.append(Pt[2])
71
72     # Make a finite difference approximation for the derivative
73     dP = (Pz[0]-Pz[1])/(2*delta_z*c)
74
75     # Calculate Born charge
76     born_charge = volume*dP
77
78     # Add the value (in units of electron charge) to the list 'bornCharges'
79     bornCharges[nAtom] = born_charge.inUnitsOf(elementary_charge)
80
81
82
83 # Finally print out the results
84 print('')
85 print('+-+-----+')
86 print('| Born effective charges (e) |')
87 print('+-+-----+')
88
89 for nAtom in range(numberOfAtoms):
90     print(' %2s' %elements[nAtom].symbol() + ' :      %4.4f      ' %bornCharges[nAtom] )
91
92 print('+-+-----+')
93 print(' Sum :      %4.4f      ' %numpy.sum(bornCharges))
94 print('+-+-----+')

```

- The script starts reading the results from the previous calculation. This will serve as a good starting guess for the DFT calculations to be performed later in the script (where the atoms are displaced).
- Extract the fractional coordinates, the list of elements, the lattice, and the calculator from the configuration, and define a few convenient variables such as the unit cell volume and the length of the C lattice vector.

- The parameter **delta_z** is the fractional displacement when calculating the derivatives.
- There are two for loops in the script. The outer loop runs over the atoms in the unit cell, and the inner one (over the variable *s*) performs the displacements in the positive and negative *z*-direction.
- At the end of the script, the results are printed out.

Running the script

- Download the above `born_charges.py` script and save it in the **Project Folder**.
- Drag the script to the **Job Manager** to run it.
- When the job is finished, the calculated Born effective charges are written in the `born_charges.log` file.
- As indicated by the calculated sum of the Born effective charges, the calculated values fulfill the acoustic sum rule

$$\sum_s Z_{s,ij}^* = 0$$
 with only a small error.

You have already got all the components you needed to compute to calculate

e_{33} . By substituting the computed values in the formula for

e_{33} , you will obtain

$e_{33} = 1.464 \text{ C/m}^2$, which is in good agreement with the value 1.4849 C/m^2 calculated above and with the value found in the literature (1.464 C/m^2) ^[1].
